

Report Date: 9/4/2015

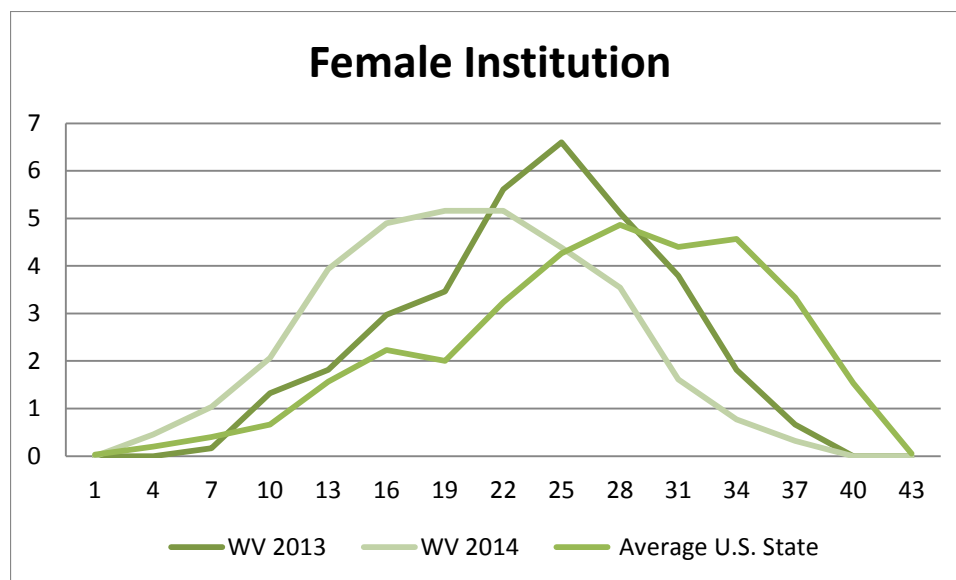

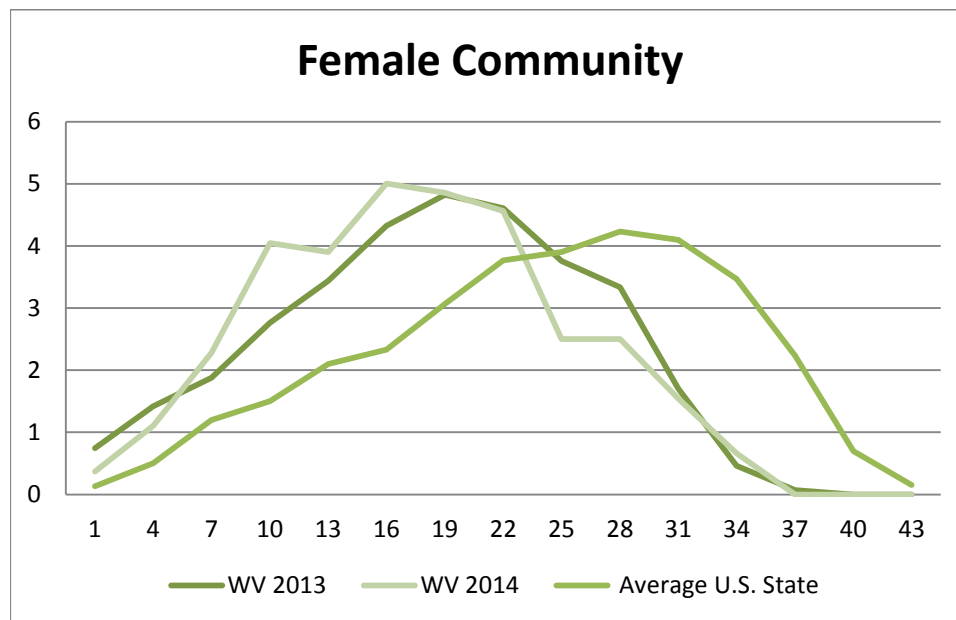

The Level of Service/Case Management Inventory is a risk and needs assessment tool which is routinely used by correctional staff to assess the likelihood that offenders will commit new offenses if released into the community. It generates a quantifiable risk score, which ranges from 0-43, with higher values indicating a greater likelihood of reoffending. The following figures summarize the risk scores for different offender populations in West Virginia and the average U.S. state.

Male Community Samples

Male Institution

Sources: Risk scores are provided by an online database managed by Multi-Health Systems, the publisher of the LS/CMI risk assessment tool. The database contains risk scores from all assessments conducted on offenders housed in regional jails, state prisons and day report centers. It does not include the results of risk assessments conducted on probationers.

Findings: For all offender populations, risk scores for West Virginia offenders are generally lower than those for offenders in the average U.S. state. This indicates that, on average, offenders housed in correctional facilities in West Virginia have a lower risk of reoffending than their counterparts in other states.
